

Selected Work

Three ways I approach a problem: commercially, operationally, and in code.

I'm an IT professional who's passionate about music, TV, and other media. This piece shows how I approach a problem operationally: a case study genericized from real change-governance work, covering service taxonomy design, structured intake, and audit-ready traceability.

Service governance

Change Process Transformation - Intake to Closure

Genericized from real change-governance work: turning inconsistent change intake into a structured, audit-ready process.

- Defines a who / why / what / when intake structure so every change is traceable by default, not reconstructed after the fact
- Includes a formal freeze-calendar exception path for quarter-end and holiday change windows
- Sample requirements written as testable user stories with Given/When/Then acceptance criteria

Context

An enterprise technology team manages change requests for team-owned applications through a service management platform. Change intake was inconsistent - requests sometimes missing ownership, justification, or a clear deployment window - leading to changes landing outside authorized windows and unclear accountability when something broke.

Current state → future state

Dimension	Current	Future
Intake	Free-text, inconsistent detail	Structured - ownership, justification, scope, impact, window required
Ownership	Often unclear requester vs. executor	Explicit who/why/what/when on every request
Change windows	Ad hoc	Authorized windows enforced at the governance layer
Freeze periods	No formal process	Defined freeze calendar with documented exception path
Audit trail	Reconstructed manually	Audit-ready by default

Service taxonomy

Standard - pre-approved, low-risk, repeatable. **Normal** - requires review against the four-part intake structure. **Emergency** - expedited incident path, retroactive justification within 24 hours.

Sample requirement

As a change reviewer, I want every submitted change request to include an accountable owner, business justification, and deployment window, so that I can assess risk without chasing missing information.

Acceptance criteria: Given a change request is submitted, when the owner or deployment window field is blank, then the system blocks submission and prompts for the missing field. Given a complete request is submitted, when it is reviewed, then the reviewer can approve, reject, or request more information without leaving the request record.

UAT & traceability

Validated the intake structure against three historical change types (standard config change, cross-system dependency change, simulated freeze-period exception) to confirm required-field logic and freeze-calendar checks behaved as specified before team-wide rollout. Each requirement maps to a specific intake field or approval-path rule, so a change record's audit trail traces back to the governance requirement it satisfies.

All company names, products, and datasets above are fictional or synthetic, built to demonstrate approach rather than represent real work product.
